

Example usage of Mega2R

Robert V. Baron and Daniel E. Weeks

6/19/2017

1 Load Libraries

```
""{r load_libraries,message=FALSE}
""
```

2 Tutorial directory and files

The files you will need for this tutorial are in the mega2rtutorial directory. You should `cd` there to do these exercises. You should see the following files:

MEGA2.BATCH.seqsimr	MEGA2.BATCH.srdta	MEGA2.BATCH.vcf
Mega2r.map	Mega2r.ped	mega2r.Rmd
mega2r.pdf	seqsimr.db	

```
# Print the working directory
getwd()

## [1] "/Users/rbaron/mega2/bb/srcdir/R/mega2rtutorial"

# Print the files
list.files(pattern = "mega2.*|seqsimr.db", ignore.case = TRUE)

## [1] "MEGA2.BATCH.seqsimr" "MEGA2.BATCH.srdta" "MEGA2.BATCH.vcf"
## [4] "Mega2r.map"          "Mega2r.ped"        "mega2r.Rmd"
## [7] "mega2r.pdf"          "mega2r_cache"      "seqsimr.db"
## [10] "seqsimr.db.old"
```

3 Installation

To run these exercises, you should install the CRAN packages *mega2r*, *mega2vcf*, *mega2genabel* and *mega2pedgene**. Once they are in CRAN, the preferred way to install will be to use the `install.packages()` command. For now, we prefer to use devtools in R; as in

```
devtools::install("../mega2r")

## Installing mega2r
## '/Library/Frameworks/R.framework/Resources/bin/R' -no-site-file \
## -no-envir -no-save -no-restore -quiet CMD INSTALL \
```

```
## '/Users/rbaron/mega2/bb/srcdir/R/mega2r' \
## -library='/Library/Frameworks/R.framework/Versions/3.3/Resources/library' \
## -install-tests
##

devtools::install("../mega2pedgene")

## Installing mega2pedgene
## '/Library/Frameworks/R.framework/Resources/bin/R' -no-site-file \
## -no-envirion -no-save -no-restore -quiet CMD INSTALL \
## '/Users/rbaron/mega2/bb/srcdir/R/mega2pedgene' \
## -library='/Library/Frameworks/R.framework/Versions/3.3/Resources/library' \
## -install-tests
##

devtools::install("../mega2vcf")

## Installing mega2vcf
## '/Library/Frameworks/R.framework/Resources/bin/R' -no-site-file \
## -no-envirion -no-save -no-restore -quiet CMD INSTALL \
## '/Users/rbaron/mega2/bb/srcdir/R/mega2vcf' \
## -library='/Library/Frameworks/R.framework/Versions/3.3/Resources/library' \
## -install-tests
##

devtools::install("../mega2genabel")

## Installing mega2genabel
## '/Library/Frameworks/R.framework/Resources/bin/R' -no-site-file \
## -no-envirion -no-save -no-restore -quiet CMD INSTALL \
## '/Users/rbaron/mega2/bb/srcdir/R/mega2genabel' \
## -library='/Library/Frameworks/R.framework/Versions/3.3/Resources/library' \
## -install-tests
##
```

Certainly,

```
R CMD install mega2r
R CMD install mega2pedgene
R CMD install mega2vcf
R CMD install mega2genabel
```

will work, too. It may generate warnings about non-package related items in the tree. All these packages may fetch other dependent CRAN packages. We also require Bioconductor Annotations that must be loaded manually. The first line loads the Bioconductor loader and the next two lines load two annotation databases. One for gene transcript locations and one to map gene names to the entrez gene IDs. (Note: You may choose a different transcript database from Bioconductor or construct one of your own.) Please type in R:

```
source("https://bioconductor.org/biocLite.R")

## Bioconductor version 3.4 (BiocInstaller 1.24.0), ?biocLite for help
## A new version of Bioconductor is available after installing the most
## recent version of R; see http://bioconductor.org/install

biocLite("TxDb.Hsapiens.UCSC.hg19.knownGene")

## BioC_mirror: http://bioconductor.org
```

```
## Using Bioconductor 3.4 (BiocInstaller 1.24.0), R 3.3.3 (2017-03-06).
## Installing package(s) 'TxDb.Hsapiens.UCSC.hg19.knownGene'
## installing the source package 'TxDb.Hsapiens.UCSC.hg19.knownGene'
## Old packages: 'DBI', 'R6', 'RSQLite', 'RcppEigen', 'XML', 'backports',
## 'devtools', 'gdata', 'jsonlite', 'rmarkdown', 'survey', 'tibble'

biocLite("org.Hs.eg.db")

## BioC_mirror: https://bioconductor.org

## installing the source package 'org.Hs.eg.db'
## Old packages: 'DBI', 'R6', 'RSQLite', 'RcppEigen', 'XML', 'backports',
## 'devtools', 'gdata', 'jsonlite', 'rmarkdown', 'survey', 'tibble'
```

4 Example Data

We have chosen to use the SeqSIMLA2 program to generate a data set for us. We needed to sub-sample the data down to 1,380 people and 1,000 markers to make the size manageable. These data will be used to illustrate Mega2 and Mega2R operations that follow.

Note: This simulator only produces markers on chromosome 1.

5 Using Mega2R packages

5.1 Creating a Mega2 database

We have provided files in the mega2rtutorial directory, that contain the data from the simulation. These files are in PLINK ped format data for 1,380 samples with 1,000 markers:

```
seqsimr.ped
seqsimr.map
```

You will need to obtain the Mega2 program <https://watson.hgen.pitt.edu/register/>. First, you will invoke Mega2 on your data. To make matters simple, we will use a pre-constructed Mega2 batch file to automate the processing by Mega2. To run Mega2 to process and create the SQLite3 database 'seqsimr.db', we issue this Unix command:

```
system("mega2 MEGA2.BATCH.seqsimr", intern=TRUE)

```

If you do not provide the argument, Mega2 will proceed to ask a series of questions to collect the needed information to produce a database. In addition, it will create a Mega2.BATCH file, we've suggested you use. You can look at the "Quick Start" documentation https://watson.hgen.pitt.edu/docs/mega2_html/mega2.html Section 4. to better understand the interactive process.

This MEGA2.BATCH.seqsimr file begins with a rather long comment indicating the keyword values that may be set and their default value. Toward the end of the file, we set the inputs as **Mega2r.ped** and **Mega2r.map**, indicate the input is PLINK ped format with parameters, and indicate that Mega2 should produce a database called **seqsimr.db**, etc. (These particular items are in bold face text below.)

```
Input_Database_Mode=1
Input_Format_Type=4
Input_Pedigree_File=Mega2r.ped
Input_PLINK_Map_File=Mega2r.map
Output_Path=.
Input_Path=.
PLINK_Args= --cM --missing-phenotype -9 --trait default
Input_Untyped_Ped_Option=2
Input_Do_Error_Sim=no
AlleleFreq_SquaredDev=999999999.000000
Value_Marker_Compression=1
Analysis_Option=Dump
Value_Missing_Quant_On_Input=-9.000000
Value_Missing_Affect_On_Input=-9
Count_Genotypes=4
Count_Halftyped=no
Value_Genetic_Distance_Index=0
Value_Genetic_Distance_SexTypeMap=0
Value_Base_Pair_Position_Index=1
Default_Reset_Invalid=no
DBfile_name=seqsimr.db
Default_Outfile_Names=yes
```

You will eventually have to run Mega2 to convert your data. But if you want to temporarily avoid the above processing, notice that in the mega2rtutorial directory, there is a seqsimr.db file.

5.2 Reading a Mega2 database into R

After you have the database, start up the R program. The first R commands you should type are:

```
library(mega2r)
ENV = read.Mega2DB("seqsimr.db", verbose = TRUE)
```

The first argument should be the path to the database. Providing the optional argument, verbose, causes the read function to summarize the tables created, their fields and their sizes. Finally, an "R environment" that contains the database tables is returned. (If you are unfamiliar with environments, you can think of them as data frames. In fact, ENV\$locus_table will access the locus_table variable from ENV as though fetching an "observation" from a data frame. The difference is when you change a data frame passed to a function, the change does not affect the original data frame. Only the function's local value is changed; ALL changes are forgotten when the function exits. If you change the data in an environment passed to a function, the change is permanent.)

```
library(mega2r)
ENV = read.Mega2DB("seqsimr.db", verbose = TRUE)

## int_table 34 3
## int_table pId key value
##
## pedigree_table 20 8
## pedigree_table pId Num EntryCnt Name PedPre OriginalID origped pedigree_link
```

```
##
## person_table 1380 11
## person_table pId UniqueID OrigID FamName PerPre ID Father Mother Sex pedigree_link person_link
##
## pedigree_brkloop_table 20 8
## pedigree_brkloop_table pId Num EntryCnt Name PedPre OriginalID origped pedigree_link
##
## person_brkloop_table 1380 11
## person_brkloop_table pId UniqueID OrigID FamName PerPre ID Father Mother Sex pedigree_link
person_link
##
## locus_table 1001 5
## locus_table pId LocusName Type AlleleCnt locus_link
##
## allele_table 2002 5
## allele_table pId AlleleName Frequency indexX locus_link
##
## marker_table 1000 7
## marker_table pId MarkerName pos_avg pos_female pos_male chromosome locus_link
##
## markerscheme_table 1000 4
## markerscheme_table pId key allele1 allele2
##
## map_table 2000 6
## map_table pId marker map position pos_female pos_male
##
## mapnames_table 2 6
## mapnames_table pId map sex_averaged_map male_sex_map female_sex_map name
##
## traitaff_table 1 4
## traitaff_table pId ClassCnt PenCnt locus_link
##
## affectclass_table 1 9
## affectclass_table pId MaleDef FemaleDef AutoDef MalePen FemalePen AutoPen locus_link class_link
##
## phenotype_table 1380 4
## phenotype_table pId person_link bytes data
##
## genotype_table 1380 5
## genotype_table pId person_link chr bytes data
```

We need to make two observations that apply to all Mega2R functions: The first is that when `verbose` is set in the initial `read.Mega2DB`, the value will be remembered. It may be used by any subsequent function. If `verbose` is `TRUE`, Mega2R functions will possibly print out far more diagnostic information than you might need, especially on subsequent runs. The second is that all Mega2R functions that do not return an environment, need to have an environment supplied as an argument. There are two ways to accomplish this. If you read "*seqsimr.db*" into the variable *seqsimr*, then you could supply as the named argument **envir** the value *seqsimr* in the Mega2R function as in:

```
showMega2ENV(envir = seqsimr)
```

The second choice is a bit of a "hack" but it is very convenient. Every Mega2R function (that does not return an environment) has a named argument defined as

```
envir = ENV
```

as in

```
showMega2ENV = function(envir = ENV) { ... }
```

The code above, sets global variable **ENV** to the local **envir** variable. And the argument evaluation mechanism of R will support this usage; even though **ENV** is not known until runtime.

5.2.1 Back to more examples.

The **ls** function will show you all the variables in an environment. (You probably used it without arguments to show you the variables in the **.GlobalEnv**.) Type:

```
ls(ENV)

## [1] "LocusCnt"           "MARKER_SCHEME"
## [3] "PhenoCnt"           "affectclass_table"
## [5] "allele_table"       "entrezGene"
## [7] "fam"                "int_table"
## [9] "locus_allele_table" "locus_table"
## [11] "map_table"          "mapnames_table"
## [13] "marker_table"       "markers"
## [15] "markerscheme_table" "pedigree_brkloop_table"
## [17] "pedigree_table"     "person_brkloop_table"
## [19] "person_table"       "phenotype_table"
## [21] "refIndices"         "refRanges"
## [23] "traitaff_table"     "txdb"
## [25] "unified_genotype_table" "verbose"
```

5.2.2 A more informative overview of the data base can be seen by:

```
showMega2ENV()

## locus count: 1001; phenotype count: 1; compression: 2 bits
## marker count: 1000; sample count: 1380
##
## genetic and physical maps:
## map name map number
## 1 Map 0
## 2 BP 1
##
## Phenotypes:
## Index Name Type
## 1 1 default affection
##
## basic tables:
## rows cols
## affectclass_table 1 9
## allele_table 2002 5
## int_table 34 3
## locus_table 1001 5
## map_table 2000 6
## mapnames_table 2 6
```

```
## marker_table          1000    8
## markerscheme_table    1000    4
## pedigree_brkloop_table  20    8
## pedigree_table        20    8
## person_brkloop_table   1380   11
## person_table          1380   11
## phenotype_table        1380    4
## traitaff_table         1     4
##
## derived tables:
##                      rows cols
## fam                  1380    8
## markers              1000    5
## unified_genotype_table 1380    2
```

5.2.3 Use standard R commands to examine the created data frames

```
str(ENV$locus_table)

## 'data.frame': 1001 obs. of  5 variables:
## $ pId      : int  1 2 3 4 5 6 7 8 9 10 ...
## $ LocusName : chr  "default" "snp1" "snp2" "snp3" ...
## $ Type      : int  2 4 4 4 4 4 4 4 4 4 ...
## $ AlleleCnt : int  2 2 2 2 2 2 2 2 2 2 ...
## $ locus_link: int  0 1 2 3 4 5 6 7 8 9 ...
```

5.3 Running pedgene using the mega2pedgene R package

mega2pedgene is the exception that proves the rule. Rather than use the read.Mega2DB function described above and as used by all the other packages, we use init_pedgene. This function calls a utility function created for read.Mega2DB. Then it creates, edits, and rewrites the **fam** data frame to purge persons with unknown case/control status. (**fam** merges data from the pedigree_table, person_table and phenotype_table as you might expect.) Finally, it calculates and stores some values that will be used repeatedly. viz:

```
library(mega2pedgene)
ENV = init_pedgene("seqsimr.db", verbose = T)

## int_table 34 3
## int_table pId key value
##
## pedigree_table 20 8
## pedigree_table pId Num EntryCnt Name PedPre OriginalID origped pedigree_link
##
## person_table 1380 11
## person_table pId UniqueID OrigID FamName PerPre ID Father Mother Sex pedigree_link person_link
##
## pedigree_brkloop_table 20 8
## pedigree_brkloop_table pId Num EntryCnt Name PedPre OriginalID origped pedigree_link
##
## person_brkloop_table 1380 11
## person_brkloop_table pId UniqueID OrigID FamName PerPre ID Father Mother Sex pedigree_link
person_link
```

```
##
## locus_table 1001 5
## locus_table pId LocusName Type AlleleCnt locus_link
##
## allele_table 2002 5
## allele_table pId AlleleName Frequency indexX locus_link
##
## marker_table 1000 7
## marker_table pId MarkerName pos_avg pos_female pos_male chromosome locus_link
##
## markerscheme_table 1000 4
## markerscheme_table pId key allele1 allele2
##
## map_table 2000 6
## map_table pId marker map position pos_female pos_male
##
## mapnames_table 2 6
## mapnames_table pId map sex_averaged_map male_sex_map female_sex_map name
##
## traitaff_table 1 4
## traitaff_table pId ClassCnt PenCnt locus_link
##
## affectclass_table 1 9
## affectclass_table pId MaleDef FemaleDef AutoDef MalePen FemalePen AutoPen locus_link class_link
##
## phenotype_table 1380 4
## phenotype_table pId person_link bytes data
##
## genotype_table 1380 5
## genotype_table pId person_link chr bytes data
```

Mega2R has an internal default list of the chromosome and base pair ranges for a number of gene transcripts. These transcripts come from the UCSC Genome Browser reference assembly GRCH37. The list was further modified to eliminate multiple records of the same gene with the exact same transcript start and transcript end. This constitutes about 30,000 records. The function `run_pedgene` examines the first 100 transcripts and prints the results. However, our test data is from part of the first chromosome only; the first 100 transcripts find no markers to run pedgene on.

```
run_pedgene()
```

When we perform more thorough runs, below, you will see many reports of "No markers in range", but occasionally you will see a listing of a gene name, markers, and count of 1/1, 1/2 and 2/2 genotypes, viz.

```
CEP104 snp24027 1280 97 3
CEP104 snp24788 1375 5 0
```

The genotypes for these markers, along with the markers info are fed to the call back function `DOpedgene`. `DOpedgene` converts the genotype nucleotides to the count of the minor allele and then runs pedgene for several different marker weights. The results are automatically stored in a file, "k_Schaid_rare.txt". Lines in that file have a prefix of chromosome, gene, number of markers and base pair range followed by 6 p-values. Two for each of three weightings of the markers. It is printed as well.

```
chr1 CEP104 2 3728644 3773797 0.8939136 0.8047689 0.8155284 0.6827252 0.9473635 0.9365409 1
```

It would be better to run pedgene on all the default transcript entries. So type:

```
# we will skip this line for the Rmd document production because it takes too long
applyFnToRanges(DOpedgene, ENV$refRanges, ENV$refIndices, envir = ENV)
```

If you run the above test, you will see that gene ROR1 has some p-values less than 0.01, FAM129A less than 0.02, and NEK7 and IGSF21 less than 0.03. If we knew this fact to start with, and hence these were the only genes we were interested in.

NOTE: You will observe that for several genes there are a few transcripts with different start and end values. A shorter test would be

```
# turn off verbose
ENV$verbose = FALSE
applyFnToRanges(DOpedgene, ENV$refRanges[1:300,], ENV$refIndices, envir = ENV)
```

Alternatively, you may try searching by Gene. Here the default transcript database is TxDb.Hsapiens.UCSC.hg19.knownGen from Bioconductor. Of course you can change it.

```
applyFnToGenes(DOpedgene, genes_arg = c('ROR1', 'FAM129A', 'NEK7', 'IGSF21'), envir = ENV)

##
## 'select()' returned 1:many mapping between keys and columns
## 'select()' returned 1:many mapping between keys and columns
```

or

```
applyFnToGenes(DOpedgene, genes_arg = c('GDAP2'), envir = ENV)

## 'select()' returned 1:1 mapping between keys and columns
## 'select()' returned 1:many mapping between keys and columns
## Error in validObject(.Object): invalid class "dgeMatrix" object: Not a valid 'Mnumeric'
class object
```

5.4 Writing a VCF File using the mega2vcf R package

First create the directory "vcfr"; so we can keep all the generated data in one place and then load the library. Mega2VCF takes an argument which is the prefix used on all the files it generates. We have chosen to make that a path that includes a directory. Mega2VCF is explained in greater depth in the Implementation Section. The Mega2VCF function assumes the environment is contained in the global variable ENV. If this is not true supply an additional argument "envir" set to the environment you wish to use.

Note, that Mega2VCF will create the expected .vcf file as well as a .fam file (we do linkage), a .phe file (phenotypes) and a few others. These files are listed below. Creating the VCF file and related files is accomplished by typing:

```
if (! dir.exists("vcfr")) dir.create("vcfr")
library(mega2vcf)
Mega2VCF("vcfr/vcf.01", ENV$markers[ENV$markers$chromosome==1 ,])
list.files("vcfr")

## [1] "vcf.01.fam" "vcf.01.freq" "vcf.01.map" "vcf.01.pen" "vcf.01.phe"
## [6] "vcf.01.vcf"
```

Read the package code to see how these files are created from the data frames.

5.5 Creating a GenABEL gwaa.data-class object using the mega2genabel R package

GenABEL can process PLINK .tped/.tfam files with the function *convert.snp.tped* to create a gwaa.data-class object. Currently, we use this mechanism to convert our data frames to a gwaa.data-class object. The argument to Mega2GenABEL is a file name prefix that will be used to name the .tped/.fam files that are created as an intermediate to be read by GenABEL <http://www.genabel.org/> <https://cran.r-project.org/web/packages/GenABEL/index.html> to produce a GenABEL "raw" file. Then the "raw" file and a generated phenotype file are processed by *load.gwaa.data* to yield a gwaa.data-class object. (See the Implementation Section.) This task is analogous to the previous exercise. Type:

```
library(mega2genabel)

## Loading required package: GenABEL
## Loading required package: methods
## Loading required package: MASS
## Loading required package: GenABEL.data

seqsimgwaa = Mega2GenABEL("TMP")

## Reading individual ids from file 'TMP.tfam' ...
## ... done. Read 1380 individual ids from file 'TMP.tfam'
## Reading genotypes from file 'TMP.tped' ...
## ...done. Read 1000 SNPs from file 'TMP.tped'
## Writing to file 'TMPtped.raw' ...
## ... done.
## ids loaded...
## marker names loaded...
## chromosome data loaded...
## map data loaded...
## allele coding data loaded...
## strand data loaded...
## genotype data loaded...
## snp.data object created...
## assignment of gwaa.data object FORCED; X-errors were not checked!

list.files(pattern = "TMP.*")

## [1] "TMP.phe"      "TMP.tfam"      "TMP.tped"      "TMPtped.raw"

str(seqsimgwaa)

## Formal class 'gwaa.data' [package "GenABEL"] with 2 slots
## ..@ phdata:'data.frame': 1380 obs. of 3 variables:

## .. .. .. ..- attr(*, "names")= chr [1:1380] "1SAP039_H05-0107" "1SAP039_H05-0106" "1SAP039_SAP039F
## .. .. ..@ gtps        :Formal class 'snp.mx' [package "GenABEL"] with 1 slot
## .. .. .. ..@ .Data: raw [1:345, 1:1000] 59 55 55 55 ...
```

You can use any of the GenABEL provided functions on your data, `seqsimgwaa`.

Note: There are several data formats that Mega2 can read and transform into a database that are not directly acceptable to GenABEL. Any M1ega2 database that can be read into R, can be transformed to GenABEL following this example with `seqsimr.db`.

6 Regression

To verify that the R packages described above have worked correctly, we can compare their output files to those created by Mega2 itself, to verify that they are, as expected, identical. This type of testing is known as regression testing.

6.1 VCF regression

It is time to use the `MEGA2.BATCH.vcf` file from the `mega2rtutorial`.

This will use the C++ Mega2 program to populate the `vcf` directory with the same set of files that the R program created in the `vcfr` directory.

At the prompt, type:

```
system("mkdir vcf")
system("mega2 MEGA2.BATCH.vcf", intern=TRUE)
```

The abbreviated `MEGA2.BATCH.vcf` file is below (notice that there are no INPUT FILES, just a database file):

```
Input_Database_Mode=2
Align_Strand_Input=no
Output_Path=vcf
Input_Untyped_Ped_Option=2
Input_Do_Error_Sim=no
AlleleFreq_SquaredDev=999999999.000000
Analysis_Option=VCF
Value_Missing_Quant_On_Output=-9
Value_Missing_Affect_On_Output=-9
DBfile_name=seqsimr.db
Chromosome_Single=1
Traits_Combine=1 2 e
file_name_stem=vcf
human_genome_build=B37
VCF_output_file_type=1
VCF_Allele_Order=Original_Order
Default_Outfile_Names=yes
```

```

system("mkdir vcf")
system("mega2 MEGA2.BATCH.vcf", intern=TRUE)

## [6] "Files vcf/vcf.01.vcf and vcfr/vcf.01.vcf are identical"

```

6.2 GenABEL regression

This test is a bit more complicated. First, we load GenABEL and access its data:

```
library(GenABEL)
data(srdta)
```

We also load the mega2genabel library and dump the GenABEL data as PLINK .ped/.map/.phe files

```
library(mega2genabel)
dmpPed()
```

Then we run:

```
system("mega2 MEGA2.BATCH.srdta", intern=TRUE)
```

6.2.1 abbreviated contents of MEGA2.BATCH.srdata file

```
Input_Database_Mode=1
Input_Format_Type=4
Input_Pedigree_File=srdta.ped
Input_PLINK_Map_File=srdta.map
Input_Phenotype_File=srdta.phe
Output_Path=.
Input_Path=.
PLINK_Args= --missing-phenotype -9 --trait default
Input_Untyped_Ped_Option=2
Input_Do_Error_Sim=no
AlleleFreq_SquaredDev=999999999.000000
Value_Marker_Compression=1
Analysis_Option=Dump
Value_Missing_Quant_On_Input=-9.000000
Value_Missing_Affect_On_Input=-9
Count_Genotypes=4

## [198] "in a web browser."
## [199] "=====

```

Then we type T commands:

```

ENV = read.Mega2DB("srdta.db")
mega = Mega2GenABEL("TMP2")

## Reading individual ids from file 'TMP2.tfam' ...
## ... done. Read 2500 individual ids from file 'TMP2.tfam'
## Reading genotypes from file 'TMP2.tped' ...
## ...done. Read 833 SNPs from file 'TMP2.tped'
## Writing to file 'TMP2tped.raw' ...
## ... done.
## ids loaded...
## marker names loaded...
## chromosome data loaded...
## map data loaded...
## allele coding data loaded...
## strand data loaded...
## genotype data loaded...
## snp.data object created...
## assignment of gwaa.data object FORCED; X-errors were not checked!

list.files(pattern = "TMP2.*")

```

```
## [1] "TMP2.phe"      "TMP2.tfam"      "TMP2.tped"      "TMP2tped.raw"
```

mega and *srdta* should be the same *gwaa.data*-class object. You can compare them however you prefer. But, *Mega2GenABELtst* can be used to compare the phenotype and genotype data, viz. in R type:

```
Mega2GenABELtst()
```

```
## all(mega_@phdata$sex == gwaa_@phdata$sex)[1] TRUE
## all(mega_@phdata$age == gwaa_@phdata$age)[1] TRUE
## all(mega_@phdata$qt1 == gwaa_@phdata$qt1)[1] TRUE
## all(mega_@phdata$qt2 == gwaa_@phdata$qt2)[1] TRUE
## all(mega_@phdata$qt3 == gwaa_@phdata$qt3)[1] TRUE
## all(mega_@phdata$bt == gwaa_@phdata$bt)[1] TRUE
## all(mega_@phdata$default == gwaa_@phdata$default)[1] TRUE
## all(mega_@gtdata@nids == gwaa_@gtdata@nids)[1] TRUE
## all(mega_@gtdata@nsnps == gwaa_@gtdata@nsnps)[1] TRUE
## all(mega_@gtdata@nbytes == gwaa_@gtdata@nbytes)[1] TRUE
## all(mega_@gtdata@snpsnames == gwaa_@gtdata@snpsnames)[1] TRUE
## all(mega_@gtdata@chromosome == gwaa_@gtdata@chromosome)[1] TRUE
## all(mega_@gtdata@map == gwaa_@gtdata@map)[1] TRUE
## all(mega_@gtdata@male == gwaa_@gtdata@male)[1] TRUE
## all(mega_@gtdata == gwaa_@gtdata)[1] TRUE
```

7 Next steps

If you are left with questions as to how you can use Mega2R for your own research, you can:

1. Read our paper "The Mega2R suite of R packages: tools for accessing and processing common genetic data formats in R", which extends this document by providing implementation details.
2. Read the source for the packages if you understand R; the code is not particularly subtle.
3. Write to the Mega2 discussion group: <https://groups.google.com/forum/#!forum/mega2-users>
